Ocean Scale Interactions, A tribute to Bach-Lien Hua

Brest, Lundi 23 juin 2014

Il y a 40 ans que je connaissais Lien — et l'admirais.

Nos chemins s'étaient rarement croisés — après tout, elle travaillait en océanographie physique, et je m'occupais de séismes et de tsunamis...

Nous retrouvant en 2007, à l'improviste d'une rencontre à l'AGU, où elle avait présenté la prestigieuse conférence Lorenz, nous avons constaté avec fascination que la Physique du vaste Océan réservait des couplages subtils entre nos domaines, que des évènements de taille monstrueuse, tels le séisme de 2004 à Sumatra, parvenaient à révéler.

Et nous avons discuté avec enthousiasme de ces propriétés insolites qui rapprochaient nos efforts professionnels au sein des grands systèmes faisant "vivre" la Terre, à l'occasion de mes dernières et trop courtes visites à Brest jusqu'à l'été 2012.

Mais hélas, en ce triste automne de 2012, la Parque filandière veillait, et vint ravir Lien aux siens, au monde et à la science.

En hommage à celle qui fut une distante mais profonde amie, ma présentation examinera des exemples d'enregistrements insolites illustrant des couplages inattendus entre l'océan, la terre solide, et l'atmosphère.

EXTRACURRICULAR GEOPHYSICS

The occurrence of exceptional events, such as the 2004 Sumatra earthquake, occasionally gives rise to the recording of physical phenomena by instruments not designed for that purpose.

For example, a seismometer may record an air wave, a hydrophone may record a tsunami...

Such recording by "unprepared" or "incompetent" instruments often times illustrates a physical coupling between the medium of the phenomenon and that where the instrument is supposed to operate.

Such coupling being generally weak, requires a very large event (Sumatra, Maule...) to be detectable.

However, such instances of coupling are precious, since they shed light on some unsuspected properties of the physical waves and media involved.

SEISMOMETERS DETECT TSUNAMIS

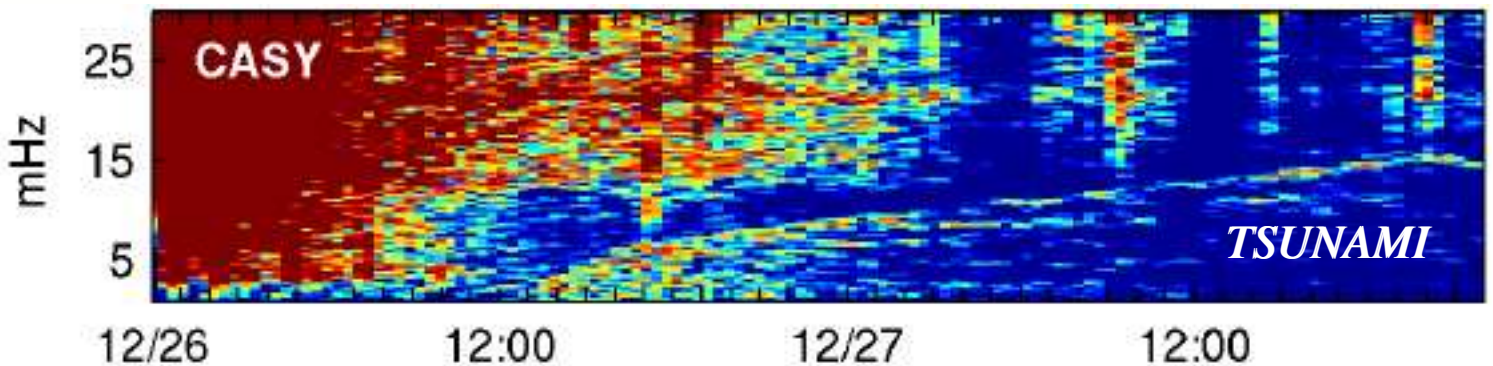

(*The Seismic "DART" ?*)

TSUNAMI RECORDED ON SEISMOMETERS

- Horizontal long-period seismometers (GEOSCOPE, IRIS...) record ultra-long period oscillations following arrival of 2004 tsunami at nearby shores [R. Kind, 2005].
- Energy is mostly between 800 and 3000 seconds
- Amplitude of equivalent displacement is **centimetric**

[Yuan et al., 2005]

[Hanson and Bowman, 2005]

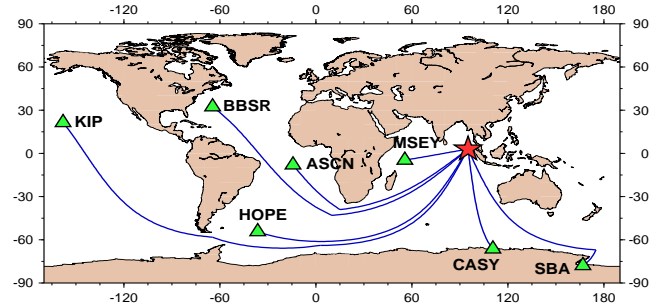

TSUNAMI RECORDED ON SEISMOMETERS (ctd.)

Enhanced Study [E.A. Okal, 2005–06].

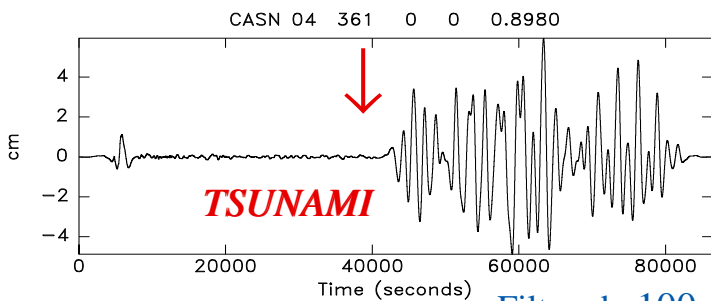

- **RECORDED WORLDWIDE** (On Oceanic shores)
- **HIGHER FREQUENCIES** (up to 0.01 Hz) **PRESENT** (in regional field)
- Tsunami detectable during **SMALLER EVENTS**
- **CAN BE QUANTIFIED**

SUMATRA 2004: TSUNAMI RECORDED ON SEISMOMETERS

- Recording by shoreline stations is **WORLDWIDE** including in regions requiring strong refraction around continents (Bermuda, Scott Base).

Casey, Antarctica, 8300 km

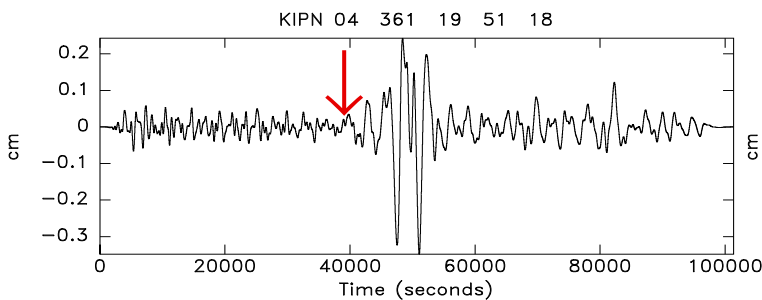

Hope, South Georgia, 13100 km

Filtered $100 < T < 10000$ s.

Kipapa, Hawaii, 27,000 km

Scott Base, Antarctica, 10400+ km

- *On some of the best records, (e.g., HOPE, South Georgia), the tsunami is actually visible **on the raw seismogram!!***

[But who "reads" seismograms in this digital age, let alone that of HOPE, South Georgia...]

Dispersed energy resolved down to $T = 80$ s.

Ile Amsterdam, 26 Dec. 2004

AISN 04 361 0 2 15.1020

Peak-to-peak = 0.233E+06 du

NOTE STRONG HIGH-FREQUENCY TSUNAMI COMPONENTS

CAN WE QUANTIFY SUCH RECORDS ?

Dispersed energy resolved down to $T = 80$ s.

Ile Amsterdam, 26 Dec. 2004

AISN 04 361 0 2 15.1020

Peak-to-peak = 0.233E+06 du

NOTE STRONG HIGH-FREQUENCY TSUNAMI COMPONENTS

CAN WE QUANTIFY SUCH RECORDS ?

1. USE NORMAL MODE THEORY

TSUNAMIS: The NORMAL MODE FORMALISM

[Ward, 1980]

- At very long periods (typically 15 to 54 minutes), the Earth, because of its finite size, can ring like a bell.
- Such *FREE OSCILLATIONS* are equivalent to the superposition of two progressive waves travelling in opposite directions along the surface of the Earth.

T = 54 minutes

"*FOOTBALL Mode*"

[After Lay and Wallace, 1995]

T = 21.5 minutes

"*BREATHING Mode*"

Ward [1980] has shown that **Tsunamis come naturally as a special branch of the normal modes of the Earth**, provided it is bounded by an ocean, and gravity is included in the formulation of its vibrations.

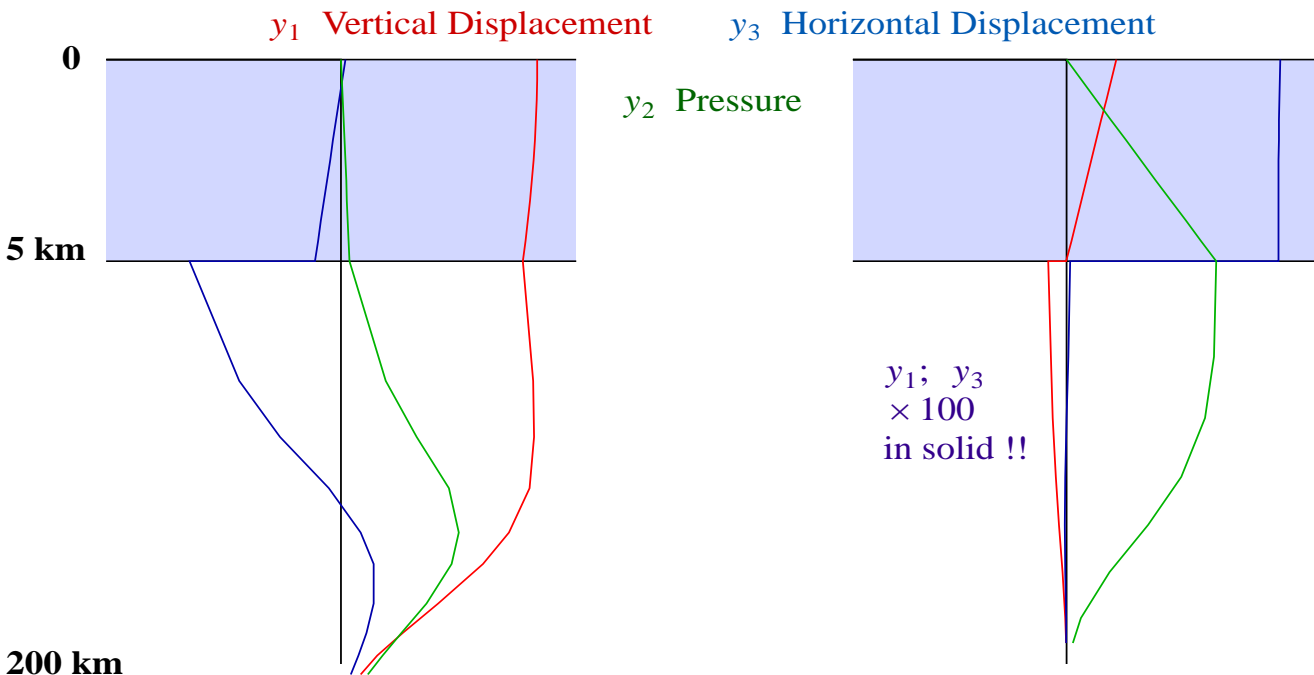

TSUNAMI as SPHEROIDAL MODE : STRUCTURE of the EIGENFUNCTION

Rayleigh Mode

$l = 200; T = 52 s$

Tsunami Mode

$l = 200; T = 908 s$

TSUNAMI EIGENFUNCTION is CONTINUED (SMALL) into SOLID EARTH

CAN WE QUANTIFY SUCH RECORDS ?

2. *MAKE SOME RATHER DRASTIC ASSUMPTIONS*

CAN WE QUANTIFY SUCH RECORDS ?

2. *MAKE SOME RATHER DRASTIC ASSUMPTIONS*

FORGET THE ISLAND (*or continent*) !!

QUANTIFYING the SEISMIC RECORD at CASY

- Assume that seismic record (e.g., at CASY) reflects response of seismometer to the *deformation of the ocean bottom*.

FORGET THE ISLAND (or continent) !

- Use *Gilbert's* [1980] combination of displacement, tilt and gravity;

Apparent Horizontal Acceleration (*Gilbert's* [1980] Notation):

$$AV = \omega^2 V - r^{-1} L (g U + \Phi)$$

or (*Saito's* [1967] notation):

$$y_3^{APP} = y_3 - \frac{1}{r \omega^2} \cdot (g y_1 - y_5)$$

- Use *Ward's* [1980] normal mode formalism;

Evaluate *Gilbert* response on solid side of ocean floor, and derive equivalent spectral amplitude of surface displacement $y_1(\omega) = \eta(\omega)$.

- Use *Okal and Titov's* [2005] Tsunami Magnitude, inspired from *Okal and Talandier's* [1989] M_m ;
- Apply to CASY record at maximum spectral energy ($S(\omega) = 4000 \text{ cm}^2 \text{ s}$ at $T = 800 \text{ s}$).

→ Find **$M_0 = 1.7 \times 10^{30} \text{ dyn} - \text{cm}$** .

Published: $1.15 \times 10^{30} \text{ dyn}^* \text{cm}$ [*Stein and Okal, 2005; Tsai et al., 2005*]

Acceptable, given the extreme nature of the approximations.

→ Suggests that the signal is just the expression of the horizontal deformation of the ocean floor, and that

CASY functions in a sense like an OBS !!

QUANTIFICATION of SEISMIC TSUNAMI RECORDS

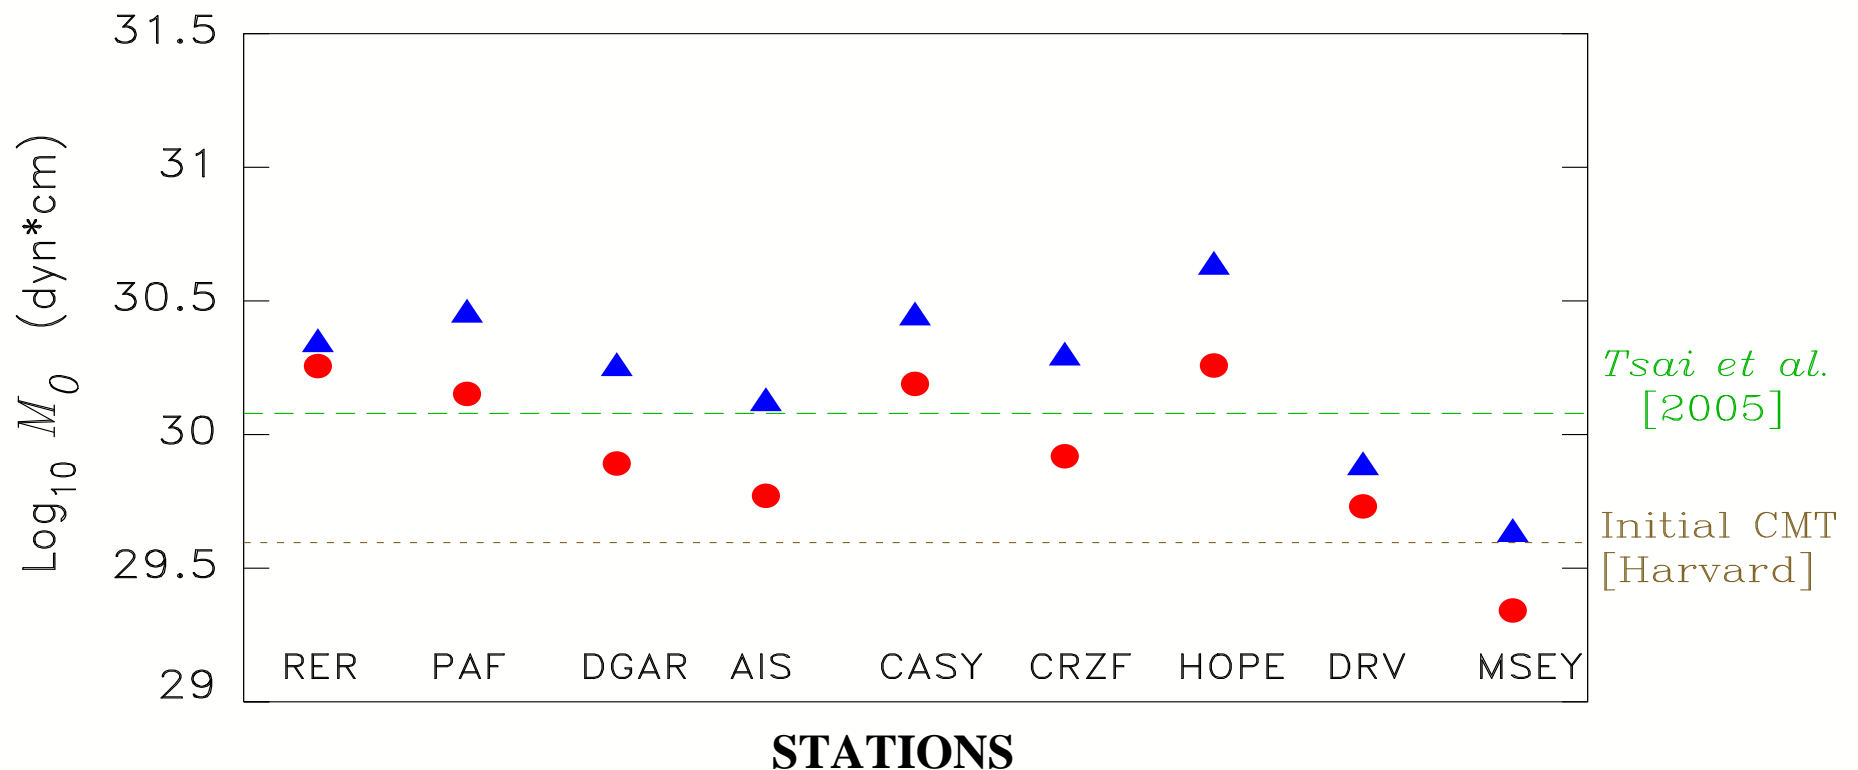

- Apply technique to dataset of 10 stations with direct great circle paths
- Use either Full Source computation (**Red Symbols**)

$$\overline{M_0} = 1.6 \times 10^{30} \text{ dyn} - \text{cm}$$

or M_{TSU} magnitude approach (**Blue Symbols**)

$$\overline{M_0} = 2.1 \times 10^{30} \text{ dyn} - \text{cm}$$

In good agreement with *Nettles et al.* [2005] and *Stein and Okal* [2005] (green dashed line)

NOTE: DRV and MSEY affected by *substantial continental shelves*.

THE FLOATING SEISMOMETER

2004 TSUNAMI RECORDED on ICEBERGS

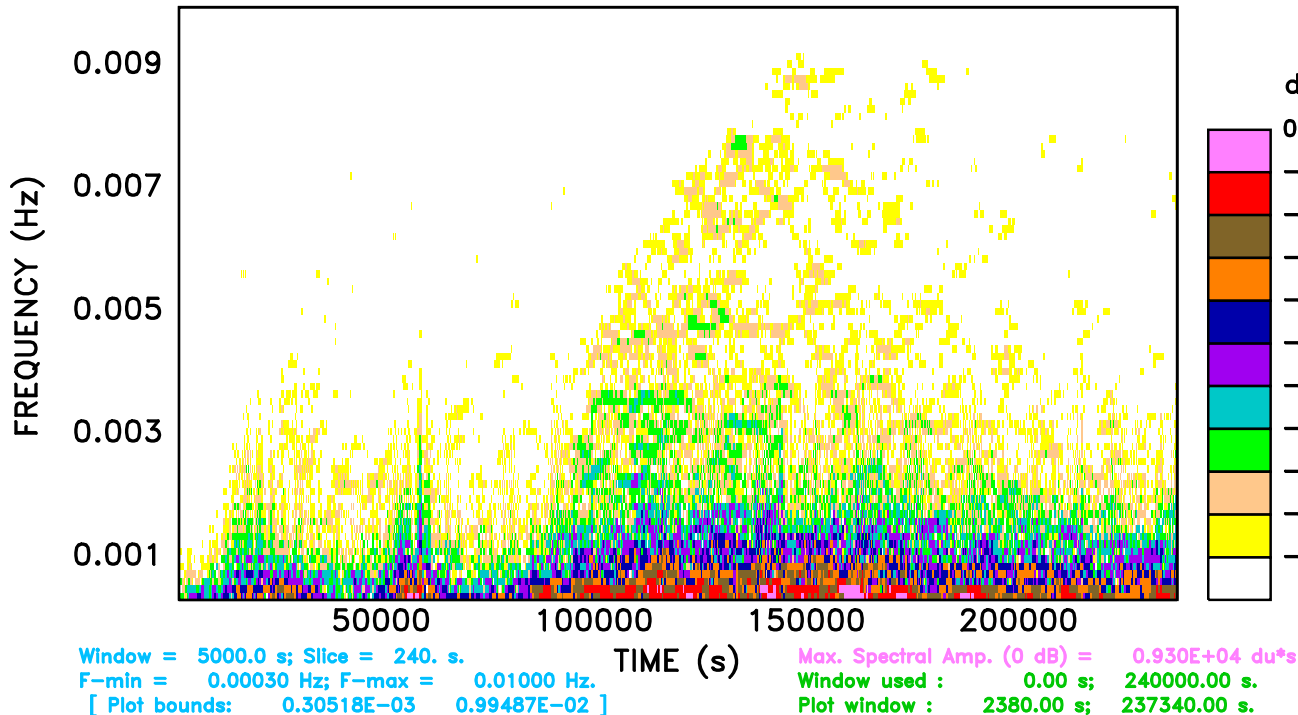

Since 2003, we had been operating seismic stations on detached and nascent icebergs adjoining the Ross Sea.

The tsunami was recorded by our 3 seismic stations, on all 3 components, with amplitudes of 10–20 cm.

NIBZ 04 360 18 0 0

PEAK-to-PEAK = 14 cm

M.H. Okal

D.R. MacAyeal

Seismic recordings of 2004 Sumatra Tsunami on Iceberg

Nascent (NIB); 26 DECEMBER 2004

This time, the iceberg (and the seismometer) float like a raft on the sea and **record directly the 3-dimensional displacement of the tsunami.**

In the Shallow-Water Approximation,

$$AR = \frac{u_x}{u_z} = \frac{1}{\omega} \sqrt{\frac{g}{h}}$$

Iceberg:

$$T = 500 \text{ s}; \quad h = 500 \text{ m} \quad AR \approx 11$$

FIRST DIRECT MEASUREMENT OF HORIZONTAL COMPONENT OF TSUNAMI ON THE HIGH SEAS

ELLIPTICITY of TSUNAMI SURFACE MOTION

(Shallow Water Approximation)

$$AR = \frac{u_x}{u_z} = \frac{1}{\omega} \sqrt{\frac{g}{h}}$$

On the high seas ($T = 1000\text{--}2000$ s; $h = 2000 - 5000$ m),

AR can be typically between **10 and 25**.

Sumatra 2004: $u_z \approx 1$ m (JASON; seismic stations)

$u_x \approx 15$ meters ?

Conceivable to use GPS-equipped ships to detect tsunami.

Ship A should see a perturbation in speed

Ship B would show a zig-zag in trajectory

CTBT HYDROPHONES

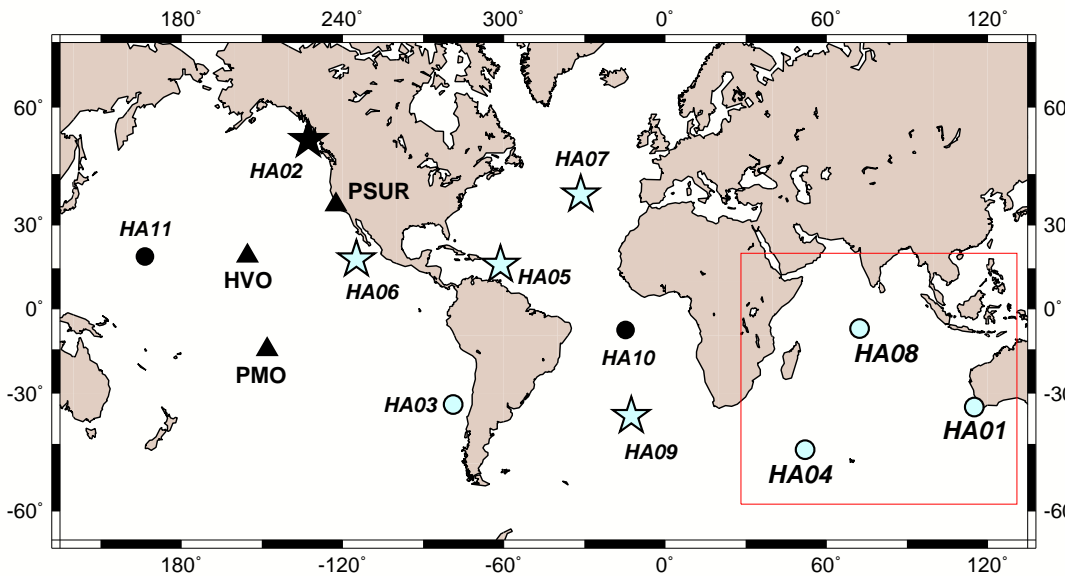

DETECT TSUNAMI

or

One Filter Too Many !

CTBT HYDROPHONE RECORDS

In the context of the CTBTO ("Test-Ban Treaty Organization"), the International Monitoring System comprises six hydrophone stations deployed in the SOFAR channel, including three in the Indian Ocean.

Diego Garcia, BIOT

Each station features several (3–6) sensors, allowing *beaming* of the array

These instruments recorded not only the hydroacoustic ("T") waves generated by the earthquake, but also its conventional seismic waves (Rayleigh), and most remarkably,

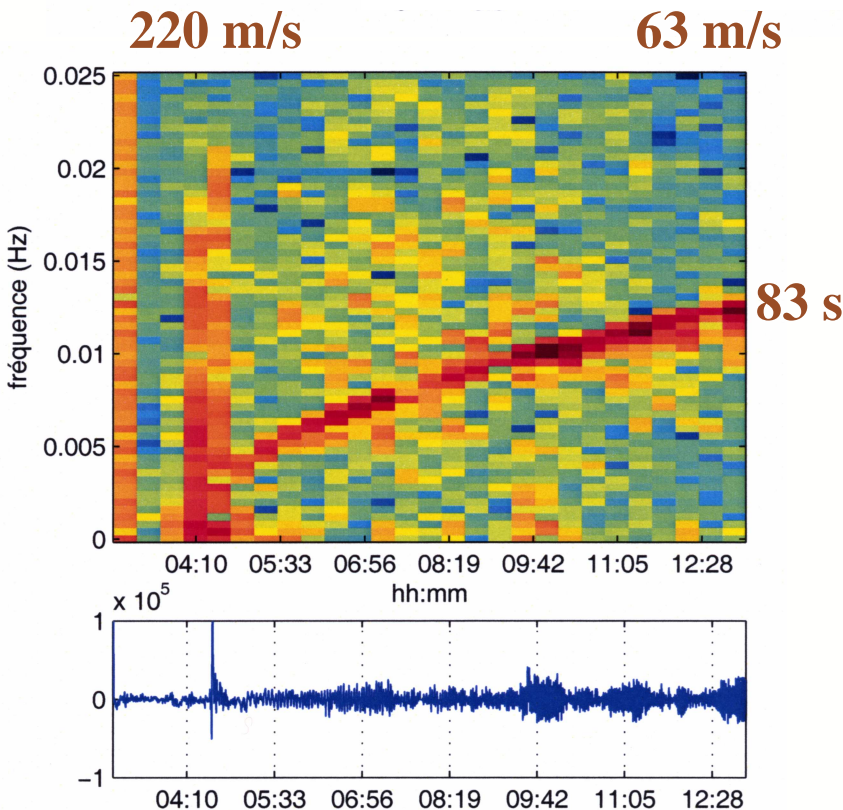

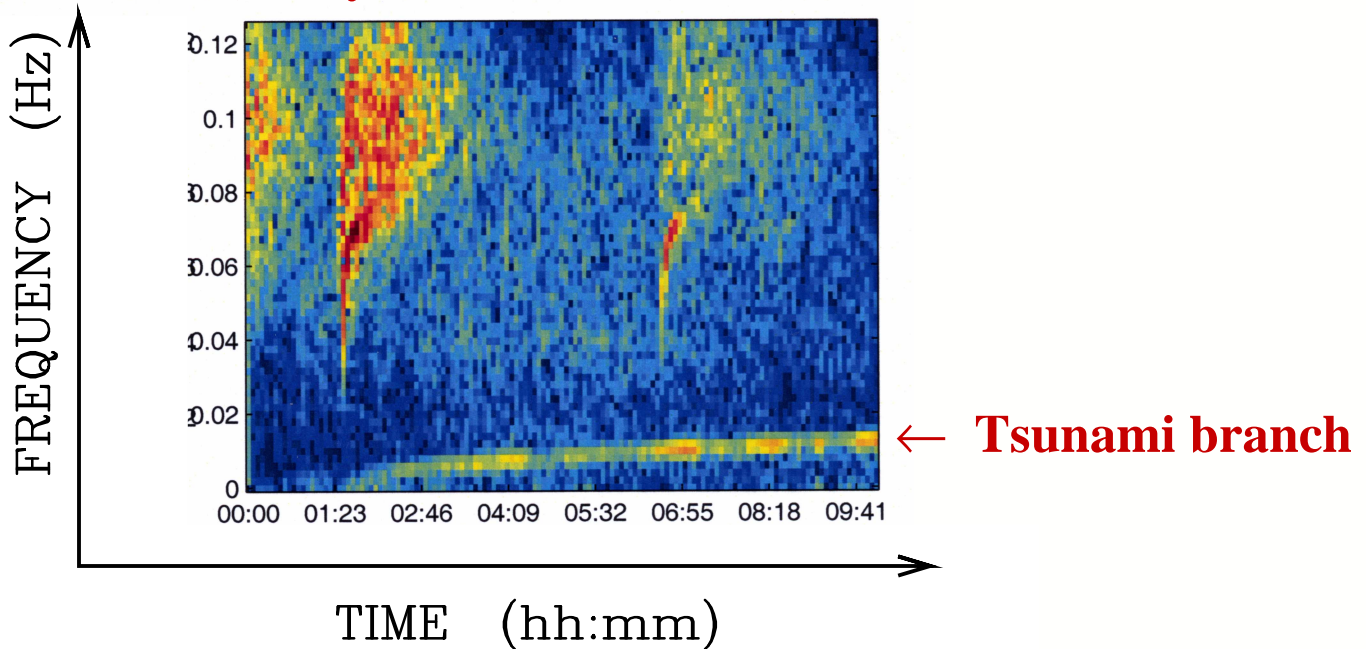

the tsunami itself.

[Okal et al., 2006]

**TSUNAMI recorded by HYDROPHONES of the CTBTO
(hanging in ocean at 1300 m depth off Diego Garcia)**

→ Instruments are severely filtered at infra-acoustic frequencies.

YET, they recorded the TSUNAMI!

Note first ever observation of *DISPERSION* of tsunami branch at *VERY HIGH* [tsunami] frequencies in the far field

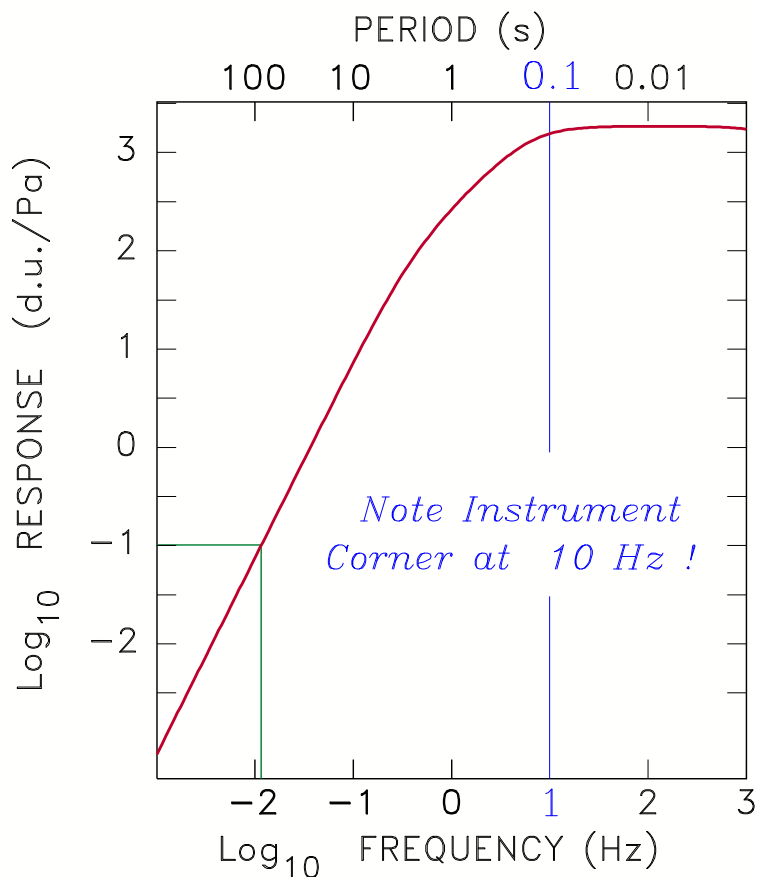

$$\omega^2 = g k \cdot \tanh(k h)$$

All of this on the high seas, unaffected by coastal response.

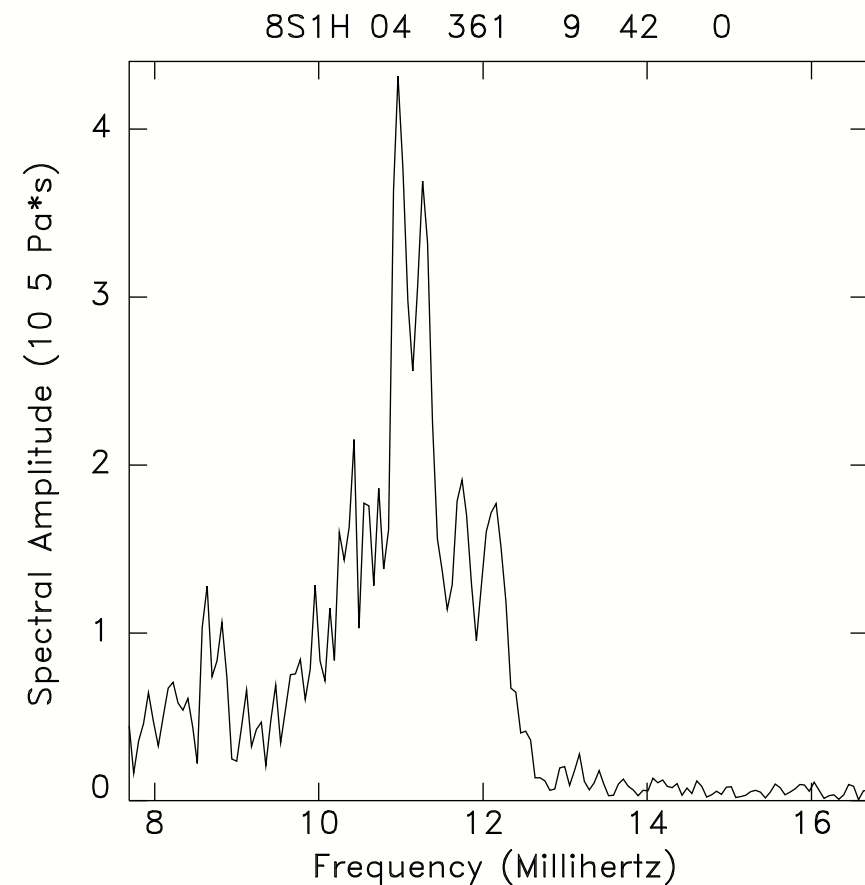

NOTE STRONG HIGH-FREQUENCY TSUNAMI COMPONENTS

Retrieving Seismic Moment from High-Frequency Tsunami Branch

- Use Hydrophone H08S1 from IMS at Diego-Garcia (BIOT)
- Deconvolve instrument and retrieve pressure spectrum

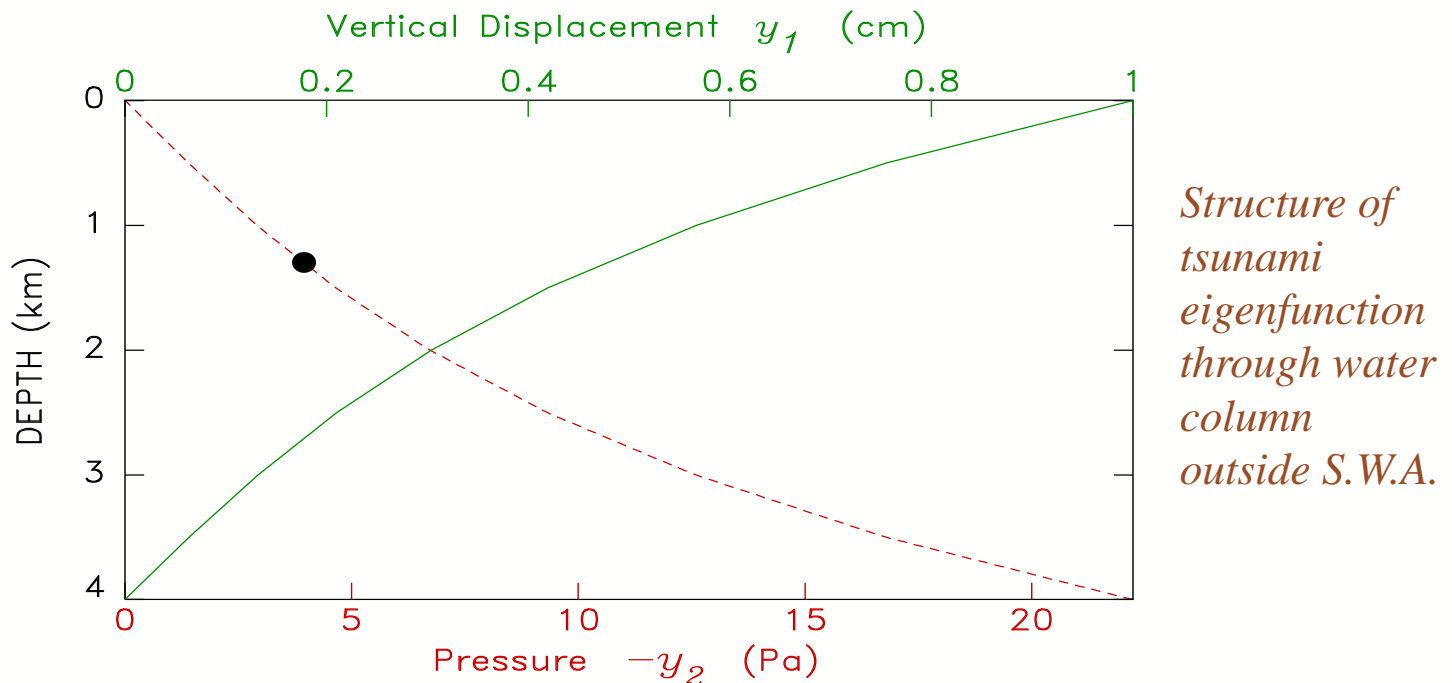

Note Instrument Response Down
by Factor 17,800 at 87 s.

$$P(\omega) = 0.35 \text{ MPa} * \text{s at } 87 \text{ s}$$

Retrieving Seismic Moment from High-Frequency Tsunami Branch (ctd.)

- Use *Okal* [1982; 2003; 2006] to convert overpressure at 1300 m depth (0.35 MPa*s) to surface amplitude η , *outside classical Shallow-Water Approximation.*

Find $\eta(\omega) = 78000 \text{ cm*s}$ at $T = 87 \text{ s}$.

- Use *Haskell* [1952], *Kanamori and Cipar* [1974], *Ward* [1980], *Okal* [1988; 2003] in normal mode formalism to compute excitation coefficients.

Find $M_0 = 8 \times 10^{29} \text{ dyn-cm}$

ACCEPTABLE !

(Moment from Earth's free oscillations: **1 to $1.2 \times 10^{30} \text{ dyn-cm}$**)

[Stein and Okal, 2005; Nettles et al., 2005]

CONCLUSION: We understand *QUANTITATIVELY* the excitation of the high-frequency components of the tsunami...

(a)

(b)

(c)

Figure 5. (a): The 50-m freighter *Soavina III* photographed on 2 August 2005 in the port of Toamasina. (b): Sketch of the port of Toamasina showing its complex geometry. (c): Captain Injona uses a wall map of the port (ESE at top) to describe the path of *Soavina III* from her berth in Channel 3B (pointed on map), where she broke her moorings around 7 p.m., wandering in the channels up to the location of the red dot (also shown on Frame b), before eventually grounding in front of the Water-Sports Club Beach (white dot; Site 17).

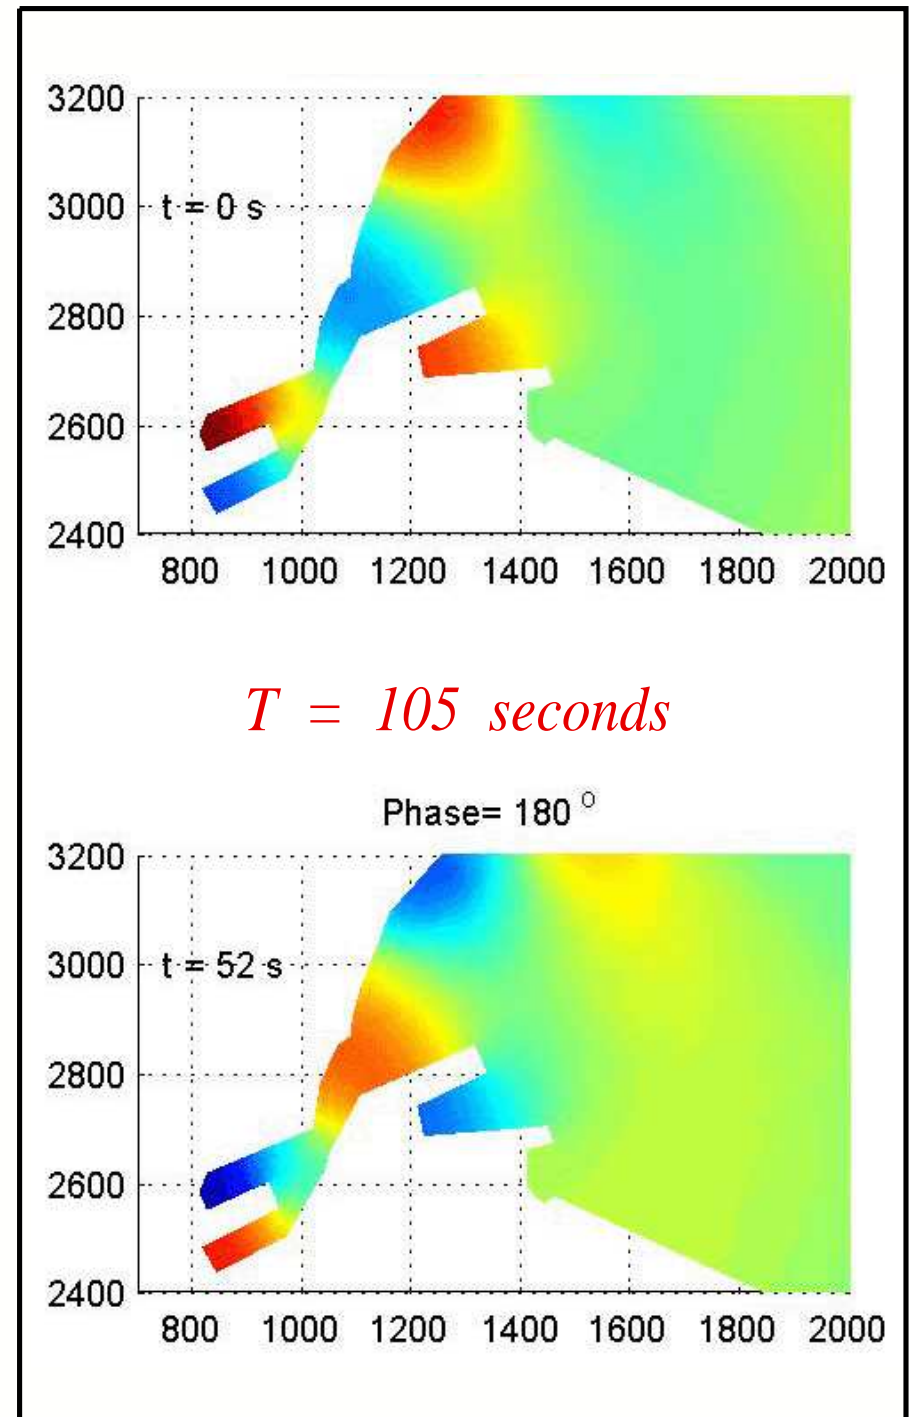

50-m SHIP BROKE MOORINGS around 19:00 (GMT+3), FOUR HOURS AFTER MAXIMUM WAVES

Preliminary modeling for Toamasina [Tamatave], Madagascar

[D.R. MacAyeal, pers. comm., 2006]

- Finite element modeling of the oscillations of the port of Toamasina reveals a fundamental mode of oscillation at $T = 105$ s, characterized by sloshing back and forth of water into the interior of the harbor, thus creating strong *currents* at the berth of *Soavina III*.
- At this period, the group velocity of the tsunami wave is found to be **97 m/s** for an average ocean depth of 4 km.
- This would correspond to an arrival at **16:55 GMT, or 19:55 Local Time.**
- This is in good agreement with the Port Captain's testimony

"After 7 p.m. and lasting several hours"

Could Ionospheric Seismology

Help Tsunami Warning ?

IONOSPHERIC RADAR DETECTS SEISMIC RAYLEIGH WAVE 150 km UP !

Tokachi Oki — 16 May 1968

Kuriles, 11 August 1969

Detected in Hawaii

WHY and HOW ?

- Atmosphere is not vacuum... and so, Rayleigh waves do not stop at a free boundary, but rather are continued upwards in the form of an pseudo-gravity wave, whose phase velocity is forced to that of the main Rayleigh wave.
- Energy density decays exponentially upwards, but since *material density decays faster*, wave amplitude can actually **increase with height** ! Radar detects variation in TEC due to perturbation of ionosphere.

WHAT ABOUT TSUNAMIS ?

- *Hines* [1972] speculates that the concept could be extended to tsunamis.

But a tsunami must displace the atmosphere as it propagates and the displaced atmosphere must respond by generating a gravity wave. The parameters are such that these waves will be of the internal type, and so will grow exponentially with height. A rise of a few metres at the surface of the water might well amplify to a few km at ionospheric heights, and that sort of amplitude could hardly escape detection if it were sought. We arrive, then, at this speculative question: If we wish to keep track of the progress of a tsunami, and so predict with some assurance the onslaught of its destructive force, might we not serve our interests best by keeping watch on the ionosphere?

Peltier and Hines [1976] elaborated on the subject, but

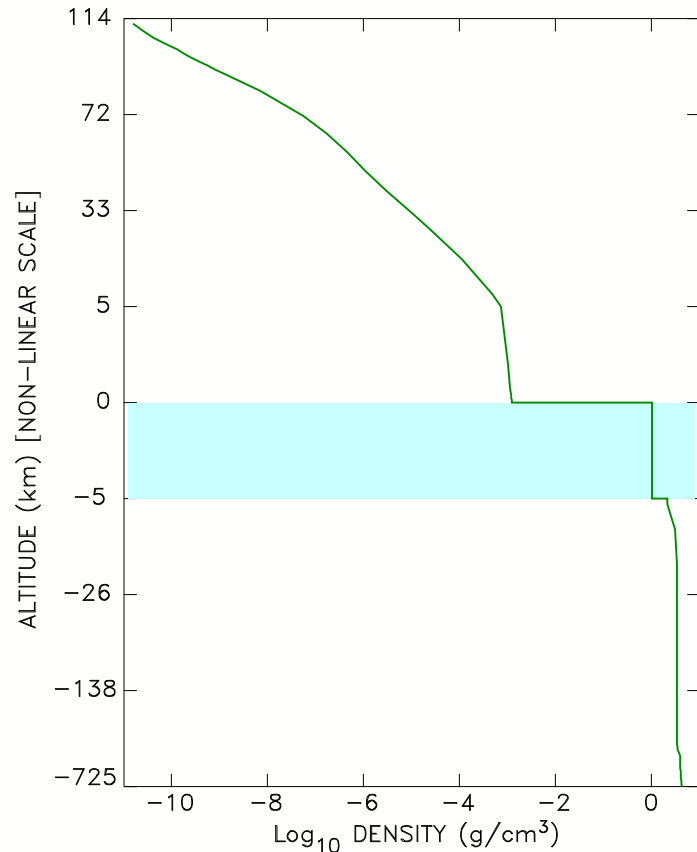

IT TOOK CLOSE TO 30 YEARS TO OBSERVE...

STRUCTURE of the TSUNAMI WAVE in the ATMOSPHERE

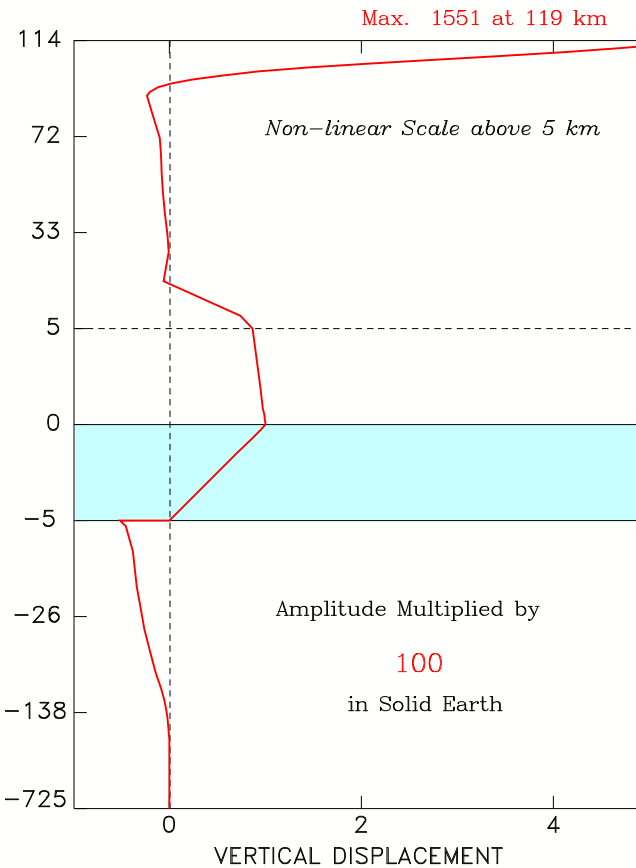

→ We compute the continuation of the tsunami wave both in the solid Earth and in the atmosphere using the generalized code "*HASH*" by *Harkrider et al.* [1974].

- Flat-layered model
- 5–km deep ocean
- Period ≈ 1000 seconds

Note large amplitude ($26 \mu\text{m/s}$) but very short duration (2.7 s).

SEISMOMETERS DETECT *T* PHASES FROM ATMOSPHERIC NUCLEAR EXPLOSIONS (ctd.)

"SUNSET" (*Operation DOMINIC*)

10 JULY 1962

Christmas Island

1 Megaton

(N) ATMOS. NUCLEAR TEST, 10 JUL 1962 PPT

Recorded at PPT, Tahiti

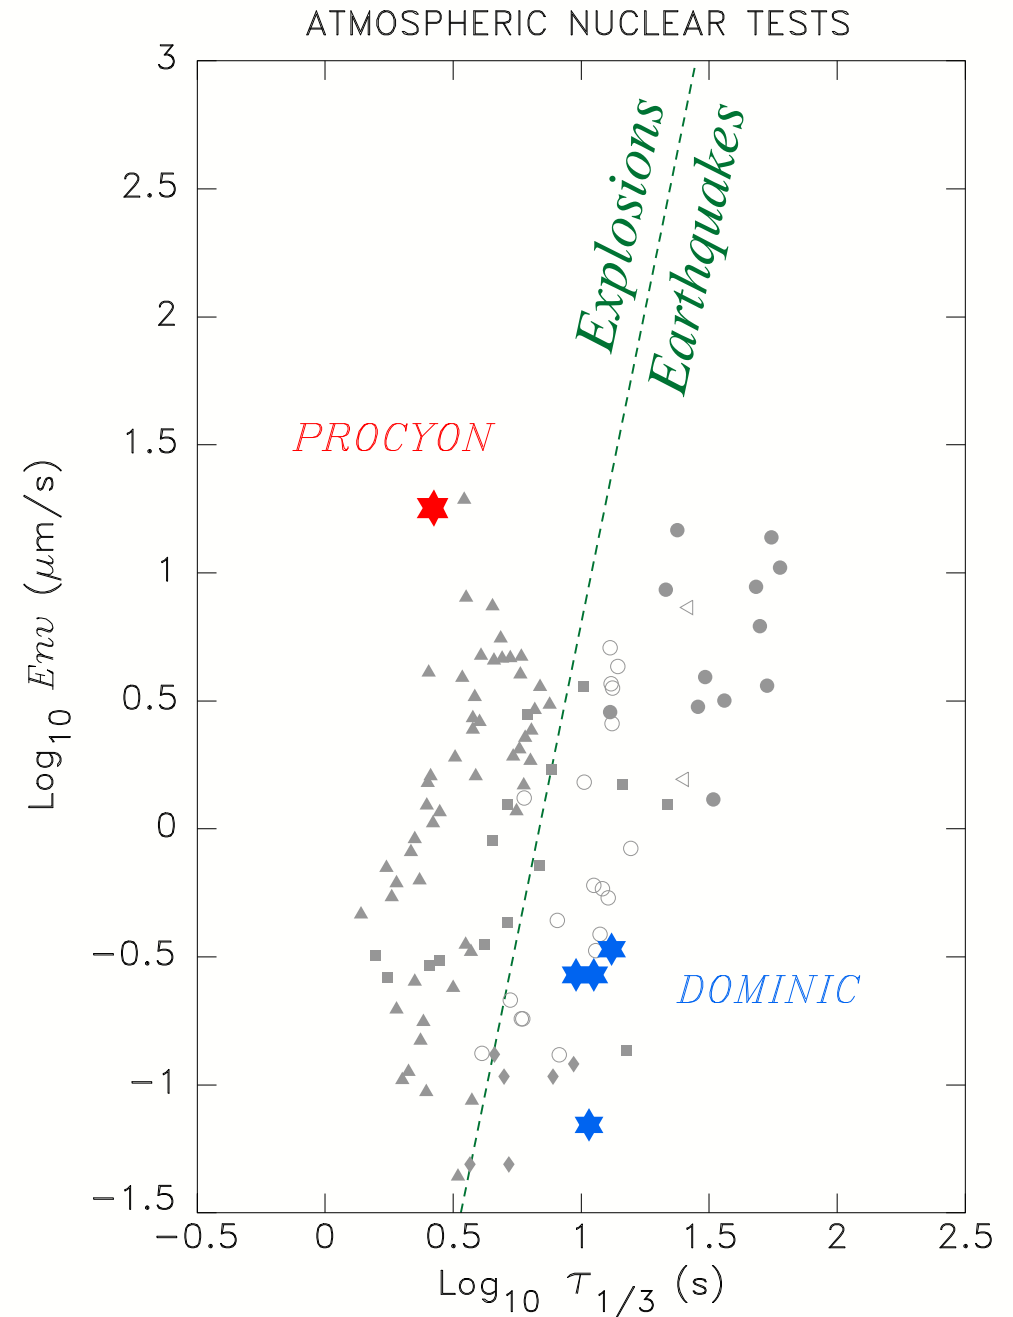

Note much smaller amplitude ($0.27 \mu\text{m/s}$) and longer duration (11.2 s).

- This difference in behavior would result in a *mis-identification* of the DOMINIC blasts as "earthquakes" using the amplitude-duration discriminant for T waves introduced by *Talandier and Okal* [2001].

→ As the T phase is probably generated by the shaking of the island structure inside the water column, itself due to the coupling of the air blast with the solid structure, the characteristics of the T wave are expected to be controlled by the geometry of the atoll, in relation to the source.

- In this respect, we note differences in the [available] characteristics of the **PROCYON** and **DOMINIC** tests: altitude (**700 m** vs. **1.7 km**), location (**over the atoll** vs. **off shore**), and to a lesser extent in the size of the atolls themselves (**154** vs. **322 km²**).

(1 Megaton; 02 OCT 1969)!*

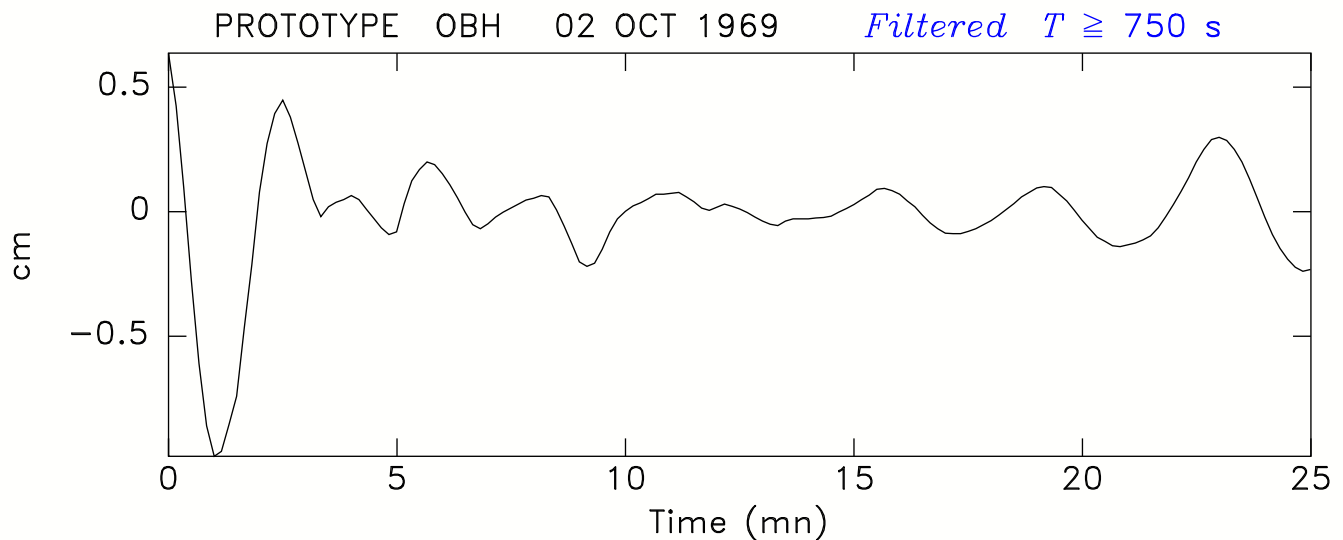

Fig. 8: Waves generated by Amchitka tests.

Tsunami Signal from the Milrow Nuclear Test (1 Megaton; 02 OCT 1969)!

CAN IT BE QUANTIFIED ?

- Once filtered this signal suggest a peak-to-peak amplitude of 1.2 cm

- Use the [outrageously simplistic] model of an explosive source 1.2 km below an ocean of depth 1800 m [as per *Vitousek and Miller, 1970*];
- Use normal mode formalism [*Ward, 1980*] to compute a synthetic maregram at distance of 0.5° ; infer an isotropic moment for Milrow: $M_0 \approx 5 \times 10^{24}$ dyn*cm;
- Use *Haskell [1967]* to derive a static *reduced displacement potential*

$$\psi(\infty) = \frac{M_0}{4\pi \rho \alpha^2} = 400,000 \text{ m}^3$$

which in turn scales to a yield

$$W = 800 \text{ kt}$$

which is only 20% smaller than the estimated yield of 1 Mt.

Given the approximations used, the agreement of the order of magnitude is

nothing short of staggering!

TSUNAMI

by

NEXT-DAY AIR ?

TSUNAMI GENERATION by *Volcanic Explosions at Sea*

Krakatoa [Sunda Straits], 27 August 1883

A catastrophic tsunami killed 35,000 people in Batavia (Jakarta). *Nomambhoy and Satake [1995]* showed that it can be well modeled by an underwater explosion.

The tsunami was reported recorded world-wide (on tidal gauges), which would seem to contradict the dispersive nature of the short wavelengths associated with sources of small dimensions...

HOWEVER ...

Press and Harkrider [1962, 1964] had shown that the tsunami is actually triggered by an **air wave** generated by an atmospheric explosion, and re-exciting the ocean as it propagates.

This explains

- the propagation of the "tsunami" along great circle paths occasionally crossing... a continent!
- the occasional early arrival of the tsunami at distant tidal stations
- and allows an estimate of the power of the explosion (100 to 150 Mt).

DIRECT "VISUAL" DETECTION of TSUNAMI on HIGH SEAS ??

- *In principle, should be impossible*

(Amplitudes too small; wavelengths too large)

YET ... ?

TSUNAMI SHADOWS — *Can we "SEE" Tsunamis, after all ?*

There exist a number of somewhat anecdotal reports of tsunamis accompanied by a "shadow" on the ocean surface.

- *Walker* [1996] has published a shot from a video lending support to this idea.

11

Figure 1. The tsunami "shadow" can be seen just below the horizon and extends across the entire field of view of the camera. Approximately 12 minutes has to be added to the time indicated based on simultaneously recorded audio of a local radio station. The video was taken at an elevation of about 50 meters above sea-level.

Godin [2003] explains this phenomenon theoretically as follows:

- Tsunami wave creates steep *gradient* in sea surface.
- This gradient affects boundary condition of lower atmosphere *wind* near surface, making it *turbulent*.
- In turn, this turbulence creates *roughness* in Sea Surface, perceived as *Tsunami Shadow*.

1138

O. A. Godin et al.: Variations in sea surface roughness induced by Sumatra-Andaman tsunami

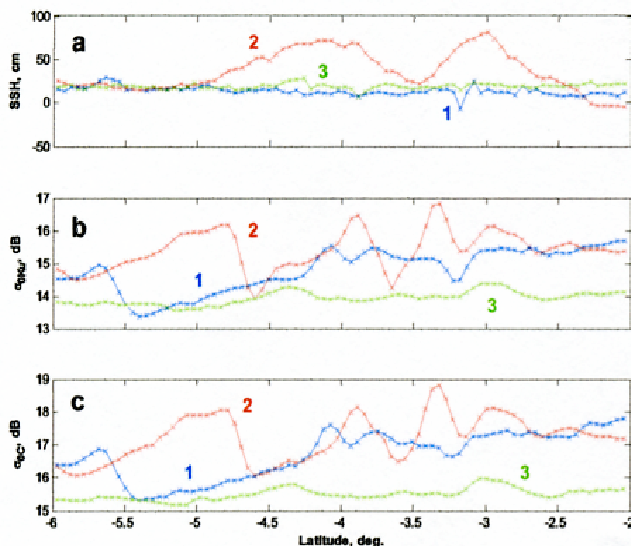

Fig. 3. Jason-1 data for pass 129 from 6° S to 2° S obtained days before (Cycle 108) (1), coincident with (Cycle 109) (2), and 10 days after (Cycle 110) (3) the Sumatra-Andaman tsunami. (a) Sea surface height. (b) Ku-band radar backscattering strength. (c) C-band radar backscattering strength.

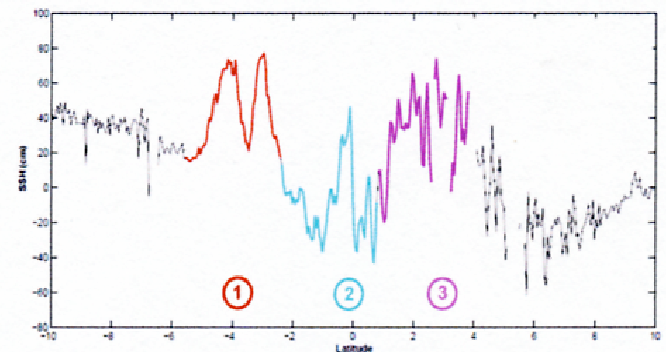

Fig. 4. Sea surface height data from Jason-1 ascending path 129 for cycle 109. Data segments 1, 2, and 3 chosen for detailed analysis of tsunami manifestations are shown in color. Breaks in the graph reflect gaps in the available SSH data.

At present, there is no universally accepted model of air flow over fast, as compared to the background wind, sea waves. Under assumptions made in (Godin, 2005), in the presence of a monochromatic tsunami wave, the wind speed relative to the ocean surface retains a logarithmic profile up

Godin et al. [2009] detect roughness in JASON altimeter records of 2004 Sumatra tsunami.

TSUNAMI DETECTED IN GEOMAGNETIC FIELD

A SENSIBLE IDEA...

- Tsunami moves water, a conducting fluid, inside the magnetic field of the Earth.
- Should create a current, which in turn, perturbs the Earth's magnetic field **B**.
- Indeed, tidal signals have been detected in daily fluctuations of **B** [e.g., McKnight, 1995].

→ Tyler [2005] showed that the perturbation b_z of the vertical component of **B** should be linked to the tsunami's amplitude η through

$$\frac{b_z}{\eta} = \frac{F_z c}{h c_s} \cdot e^{-\kappa z}$$

where F_z is the unperturbed vertical field, $c = \sqrt{g h}$ the tsunami's phase velocity, $c_s = c + i c_d$ with $c_d = 2 K / h$ and K the magnetic diffusivity ($K = 1/\mu\sigma$).

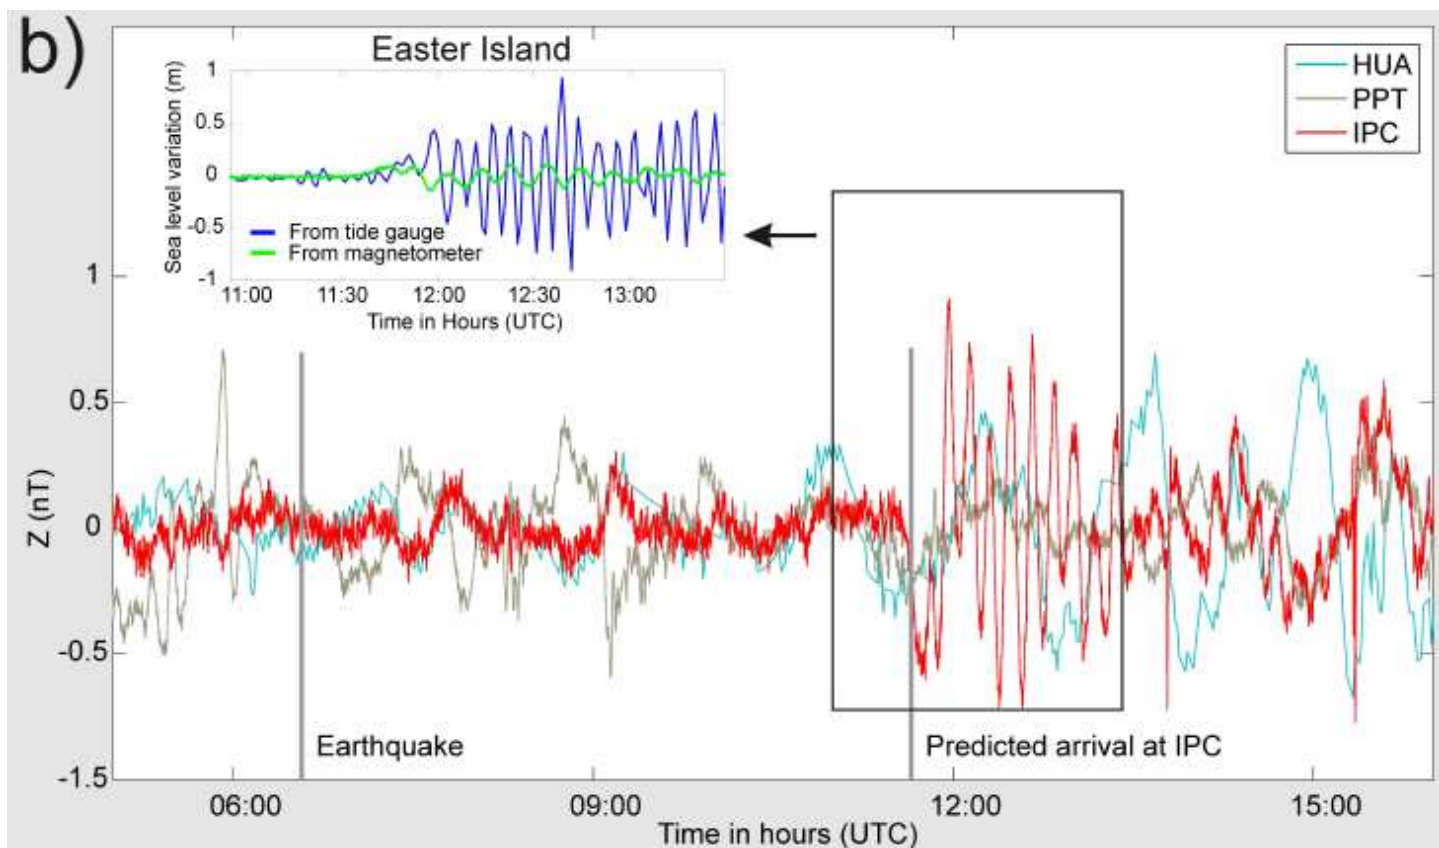

- Unfortunately, in the case of the 2004 Sumatra tsunami, the areas with maximum η are at the magnetic Equator, and no signal was detected...

→ Otherwise, one would expect about **10 to 20 nT per meter** of vertical sea surface displacement...

DETECTION DURING THE 2010 CHILEAN TSUNAMI

- *Manoj et al.* [2011] detected this effect during the 2010 Chilean tsunami using the geomagnetic station at Easter Island (IPC -- below, **red**)

→ *The amplitude detected, ≈ 1 nT, is in good agreement with that of the tsunami on the high seas (15 to 20 cm), as recorded on DART buoys.*

- They should **NOT** be comparing to a tide gauge record, which is strongly affected by harbor response.

CONCLUSIONS

- The exceptional size of the 2004 tsunami emphasizes the detailed structure of its tsunami.
- The tsunami includes significant high-frequency components (3–10 mHz), propagating outside the SWA and which are relevant to harbor response.

- The tsunami does not stop at water interfaces, but is prolonged into both the solid Earth and the atmosphere.

It fully samples the "Earth's complex system"

- This remark enables the interpretation of the tsunami as a particular case of the Earth's free oscillations; this approach allows the quantification of many secondary properties of the tsunami, as excited by a dislocation source.
- Because of the complex nature of the tsunami eigenfunction (consisting not only of a displacement field, but also of pressure, changes in gravity, tilt, etc.), many technologies can be used to detect the tsunami, using equipment already deployed.
- More work would be warranted to understand the generation of deep infrasound signals, as detected in Diego Garcia.
